We investigate the scalar meson mass dependence on the chiral phase transition in the framework of an SU(3), (axial)vector meson extended linear sigma model with additional constituent quarks and Polyakov loops. We determine the parameters of the Lagrangian at zero temperature in a hybrid approach, where we treat the mesons at tree-level, while the constituent quarks at 1-loop level. We assume two nonzero scalar condensates and together with the Polyakov-loop variables we determine their temperature dependence according to the 1-loop level field equations.

1. Introduction

The investigation of the QCD phase diagram is a very important subject both theoretically and experimentally nowadays. The ongoing and future heavy ion experiments such as RHIC, and CERN/LHC study the low density part of the phase diagram which can also be investigated theoretically by lattice QCD, at CBM/FAIR the high density part will be studied, which is still not settled theoretically, so it is worth to investigate the phase diagram thoroughly.

Our starting point is the (axial)vector meson extended linear sigma model with additional constituent quarks and Polyakov-loop variables. The

(1)
loops, was exhaustively analyzed at zero temperature in [1, 2, 3]. The Lagrangian of the model is given by,

\[
\mathcal{L} = \text{Tr}[\left(D_\mu \Phi \right)^\dagger \left(D_\mu \Phi \right)] - m_0^2 \text{Tr}(\Phi^\dagger \Phi) - \lambda_1 \left[\text{Tr}(\Phi^\dagger \Phi)\right]^2 - \lambda_2 \text{Tr}(\Phi^\dagger \Phi)^2 \\
- \frac{1}{4} \text{Tr}(L^2 + R^2) + \text{Tr} \left( \left( \frac{m_i^2}{2} + \Delta \right) (L^2 + R^2) \right) + \text{Tr}[H(\Phi + \Phi^\dagger)] \\
+ c_1 (\text{det} \Phi + \text{det} \Phi^\dagger) + i \frac{g_2}{2} \left\{ \text{Tr} \{L_{\mu\nu} [L^\mu, L^\nu] \} + \text{Tr} \{R_{\mu\nu} [R^\mu, R^\nu] \} \right\} \\
+ \frac{h_1}{2} \text{Tr}(\Phi^\dagger \Phi) \text{Tr}(L^2 + R^2) + h_2 \text{Tr} \left[ (L^2 \Phi)^2 + (\Phi R^2) \right] + 2h_3 \text{Tr}(L^2 + R^2) \Phi^\dagger \Phi \\
+ g_3 [\text{Tr}(L_L L_L L^L) + \text{Tr}(R_R R_R R^R)] + g_4 [\text{Tr} (L_L L^L L^L) + \text{Tr} (R_R R^R R^R)] + g_5 [\text{Tr}(L_L L^L) \text{Tr}(R_R R^R)] + g_6 [\text{Tr}(L_L L^L) \text{Tr}(L_L L^L) \text{Tr}(R_R R^R) + \text{Tr}(R_R R^R) \text{Tr}(R_R R^R) + \text{Tr}(R_R R^R) \text{Tr}(R_R R^R)] \\
+ \Psi i \gamma^5 \Phi \Phi - g_F \Psi (\Phi_S + i \gamma_5 \Phi_{PS}) \Psi,
\]

where

\[
D^\mu \Phi = \partial^\mu \Phi - ig_1 (L^\mu \Phi - \Phi R^\mu) - ieA_{\mu}^\mu[\Phi], \\
L^\mu = \partial^\mu L^\nu - ieA_{\nu}^\nu[\Phi], \\
R^\mu = \partial^\mu R^\nu - ieA_{\nu}^\nu[\Phi],
\]

Here \( \Phi \) stands for the scalar and pseudoscalar fields, \( L^\mu \) and \( R^\mu \) for the left and right handed vector fields, \( \Psi = (u, d, s)^T \) for the constituent quark fields, while \( H \) for the external field.

2. Parametrization

In order to go to finite temperature/chemical potential, parameters of the Lagrangian have to be determined, which is done at \( T = \mu = 0 \). For this we calculate tree-level masses and decay widths of the model and compare them with the experimental data taken from the PDG [4]. For the comparison we use a \( \chi^2 \) minimization method [5] to fit our parameters (for more details see [1]). It is important to note that in the present work we also included in the scalar and pseudoscalar masses the contributions coming from the fermion vacuum fluctuations by adapting the method of [6].

We have 14 unknown parameters, namely \( m_0, \lambda_1, \lambda_2, c_1, m_1, g_1, g_2, h_1, \), \( h_2, h_3, \delta_S, \Phi_N, \Phi_S, \) and \( g_F \). Here \( g_F \) is the coupling of the additionally introduced Yukawa term, which can be determined from the constituent quark masses through the equations \( m_{u/d} = g_F \phi_N / 2, m_s = g_F \phi_s / \sqrt{2} \).

\footnote{In the present work we use a different anomaly term \( (c_1 \text{ term}) \). This, however, does not influence the results much.}

It is worth to note that if we do not consider the very uncertain scalar-isoscalar sector $m_0$, and $\lambda_1$ always appear in the same combination $C_1 = m_0^2 + \lambda_1 (\phi_N^2 + \phi_S^2)$ in all the expressions, thus we can not determine them separately. Additionally a similar combination appears for $m_1$ and $h_1$ in the vector sector as $C_2 = m_1^2 + \frac{1}{4} (\phi_N^2 + \phi_S^2)$ (see details in [1]). The parameter values of the fit without scalars are given in Table 1. Since $\lambda_1$ and $h_1$ are undetermined they can be tuned to select the $f_0^L$ (a.k.a. $\sigma$) from the scalar spectrum (by its mass and decay widths) and its mass has, as we will see, a huge effect on the thermal properties of the model.

3. Field equations

In our approach we have four order parameters, which are the $\phi_N$ non-strange and $\phi_S$ strange condensates, and the $\Phi$ and $\bar{\Phi}$ Polyakov-loop variables. The condensates arise due to the spontaneous symmetry breaking while the Polyakov-loop variables naturally emerge in mean field approximation, if one calculates free fermion grand canonical potential on a constant gluon background. The effect of fermions propagating on a constant gluon background in the temporal direction formally amounts to the appearance of imaginary color dependent chemical potentials (for details see [7, 8]).

At finite temperature/baryochemical potential we can set up four coupled field equations for the four fields, which are just the requirements that the first derivatives of the grand canonical potential according to the fields must vanish. As a first approximation we apply a hybrid approach in which we only consider vacuum and thermal fluctuations for the fermions, but not for the bosons. We use a mean field Polyakov-loop potential $U(\Phi, \bar{\Phi})$ of a polynomial form with coefficients determined in [9]. Within this simplified

\[ \text{Since isospin symmetry is assumed, we have only two condensates: } \phi_N \text{ and } \phi_S. \]
treatment the equations are the following:

\[
- \frac{d}{d\Phi} \left( \frac{U(\Phi, \bar{\Phi})}{T^4} \right) + \frac{2N_c}{T^3} \sum_{q=u,d,s} \int \frac{d^3p}{(2\pi)^3} \left( \frac{e^{-\beta E_q^-}(p)}{g_q^-(p)} + \frac{e^{-2\beta E_q^+(p)}}{g_q^+(p)} \right) = 0, 
\]

\[
- \frac{d}{d\Phi} \left( \frac{U(\Phi, \bar{\Phi})}{T^4} \right) + \frac{2N_c}{T^3} \sum_{q=u,d,s} \int \frac{d^3p}{(2\pi)^3} \left( \frac{e^{-\beta E_q^+(p)}}{g_q^+(p)} + \frac{e^{-2\beta E_q^-(p)}}{g_q^-(p)} \right) = 0, 
\]

\[
\begin{align*}
\bar{\Phi}^2 \phi_N + \left( \lambda_1 + \frac{1}{2} \lambda_2 \right) \phi_N^2 + \lambda_1 \phi_N \phi_S^2 - h_N + \frac{g_F}{2} N_c \left( \langle u \bar{u} \rangle_T + \langle d \bar{d} \rangle_T \right) = 0, \\
\bar{\Phi}^2 \phi_S + (\lambda_1 + \lambda_2) \phi_S^2 + \lambda_1 \phi_N^2 \phi_S^2 - h_S + \frac{g_F}{\sqrt{2}} N_c \langle s \bar{s} \rangle_T = 0,
\end{align*}
\]

where

\[
\begin{align*}
g_q^+(p) &= 1 + 3 \left( \Phi + \Phi e^{-\beta E_q^+(p)} \right) e^{-\beta E_q^+(p)} + e^{-3\beta E_q^+(p)}, \\
g_q^-(p) &= 1 + 3 \left( \Phi + \Phi e^{-\beta E_q^-(p)} \right) e^{-\beta E_q^-(p)} + e^{-3\beta E_q^-(p)}, \\
E_q^\pm(p) &= E_q(p) \mp \mu_B/3, \quad E_{u/d}(p) = \sqrt{p^2 + m_{u/d}^2}, \quad E_s(p) = \sqrt{p^2 + m_s^2},
\end{align*}
\]

and

\[
\langle q\bar{q} \rangle_T = -4m_q \int \frac{d^3p}{(2\pi)^3} \frac{1}{2E_q(p)} \left( 1 - f_\phi^-(E_q(p)) - f_\phi^+(E_q(p)) \right),
\]

with the modified distribution functions

\[
\begin{align*}
f_\phi^+(E_p) &= \frac{\left( \Phi + 2\Phi e^{-\beta(E_p-\mu_q)} \right) e^{-\beta(E_p-\mu_q)} + e^{-3\beta(E_p-\mu_q)}}{1 + 3 \left( \Phi + \Phi e^{-\beta(E_p-\mu_q)} \right) e^{-\beta(E_p-\mu_q)} + e^{-3\beta(E_p-\mu_q)}}, \\
f_\phi^-(E_p) &= \frac{\left( \Phi + 2\Phi e^{-\beta(E_p+\mu_q)} \right) e^{-\beta(E_p+\mu_q)} + e^{-3\beta(E_p+\mu_q)}}{1 + 3 \left( \Phi + \Phi e^{-\beta(E_p+\mu_q)} \right) e^{-\beta(E_p+\mu_q)} + e^{-3\beta(E_p+\mu_q)}}.
\end{align*}
\]

4. Results

Solving Eqs. 2-5 we get the temperature dependence of the order parameters, which can be seen in Fig. 1. In [1] it was shown that the \( q\bar{q} \) scalar
nonet most probably contains $f_0$’s with masses higher than 1 GeV. If we set $\lambda_1 = 0$ we get $m_{f_0^L} = 1.3$ GeV, which is in agreement with [1]. However in this case we get a very high pseudocritical temperature, $T_c \approx 550$ MeV, for $\phi_N$, which is much larger than earlier results (e.g. on lattice $T_c \approx 150$ MeV [10]). Now, if we tune $\lambda_1$ to get $m_{f_0^L} = 400$ MeV (which corresponds to the physical particle $f_0(500)$), than $T_c$ goes down to 150 – 200 MeV, which can be seen in Fig. 2. This finding is in line with the results of [11], where they used a similar model, but without vector mesons. This suggests that in order to get a good pseudocritical temperature we would need a scalar-isoscalar particle with low mass ($\sim 400$ MeV), which is probably not a $q\bar{q}$ state according to [1]. In Fig. 3 and 4 we show the temperature dependence of the scalar meson masses. The mass of the parity partners ($\pi$ and $f_0^L$) reaches the same value above the phase transition temperature.
